The administration of the non-psychotropic cannabinoid cannabidiol <http://en.wikipedia.org/wiki/Cannabidiol> (CBD) leads to improvement in bone fracture healing, according to preclinical data <http://www.ncbi.nlm.nih.gov/pubmed/25801536> published online ahead of print in the *Journal of Bone and Mineral Research*.
Investigators at the Hebrew University Bone Laboratory in Israel assessed the ability of CBD administration to promote healing in rats with mid-femoral fractures. Researchers reported, “CBD markedly enhanced the biomechanical properties of the healing femora after 8 weeks.”
Authors also evaluated the administration of THC and CBD together, but reported that this combined preparation was “not advantageous” over CBD alone — indicating that the plant’s potential bone-stimulating properties are primarily specific to cannabidiol.
